

Connect WABA Flow Explanation

1. Opening the Connect WABA Page

When the user opens the Connect WABA page, the `mount()` method runs automatically. It checks whether the user has permission to connect a WhatsApp account. If permission is granted, it loads any previously saved Facebook App ID, App Secret, WABA ID, Access Token, and webhook status from the database and displays them in the UI. If a webhook verification token does not exist, it generates one and stores it. If the account is already connected, the user is redirected directly to the WABA dashboard.

2. Connecting the Webhook

When the user enters the Facebook App ID and Facebook App Secret and clicks 'Connect Webhook', the `webhookConnect()` method is executed. It first validates the inputs, stores them in the database, and then calls `connectWebhook()` from the WhatsApp trait. This is the first request sent to Meta. Meta verifies the webhook by calling the application's webhook endpoint. If verification succeeds, the application marks the webhook as connected.

3. Connecting the WhatsApp Business Account

Next, the user enters the WABA ID and Access Token and clicks 'Configure'. The `connectAccount()` method validates the values, stores them in the database, and calls `loadTemplatesFromWhatsApp()`. This sends a request to Meta's Graph API using the Access Token and WABA ID to retrieve all approved WhatsApp templates. These templates are then saved into the application's database.

4. Subscribing the WABA

After the templates are synchronized, `subscribeWebhook()` is called. This sends a request to Meta to subscribe the application to the selected WABA. From this point onward, Meta knows where to send incoming messages, delivery reports, read receipts, and template status updates. Without this subscription, the application could send messages but would not receive real-time events.

5. Opening the Dashboard

Once the connection is completed successfully, the application updates the connection status in the database and redirects the user to the WABA dashboard. From there, other modules such as Templates, Campaigns, Chat, and Analytics use the saved credentials and synchronized data. The React frontend never communicates directly with Meta. Instead, it always sends requests to the backend, and the backend securely communicates with the Meta Graph API.
